

ABSTRACT OF THE DISCLOSURE

In a method for saving personal data for a subscriber to a wireless communications network, the data is being memorized in a mobile communication station and saved in a network server by means of a first communication channel and in a first saving mode. A determination is made whether the mobile device may establish a second communication channel and/or has an other mode of saving. If so, communication is opened on the second channel and/or according to the other mode, and the data is saved by means of the second communication channel and/or the other mode.
